ABSTRACT

A study was conducted to determine the relationships between Grade A dairy producers milk production levels and size of herd and their use of 21 milk production practices recommended by the University of Tennessee. The population consisted of 405 Grade A dairymen in 42 Tennessee counties. The extension agent in each county interviewed 10 or more dairymen. The 21 recommended milk production practices were classified into groups-herd management, breeding management, forage feeding, and concentrate feeding. Milk production levels were significantly related to 14 of the 21 recommended milk production practices. A significantly greater proportion of the producers in the high than in the low milk production group were using each of the 14 recommended practices. Size of herd was significantly related to 8 of the recommended practices. Size of herd was significantly related to only one group, hera management. Level of milk production was significantly related to the total number of recommended practices used. Size of herd was not significantly related to the total number of recommended practices used. SOME FACTORS INFLUENCING DAIRY PRACTICE ADOPTION BY GRADE A MILK PRODUCERS IN SELECTED TENNESSEE COUNTIES

by

Anthony C. Griffin

March 1972

ABSTRACT

The purpose of this study was to determine the relationships between Grade A dairy producers' milk production levels and size of herd, and their use of 21 milk production practices recommended by The University of Tennessee.

The population consisted of a randomly-selected sample of 405 Grade A dairymen in 42 Tennessee counties where 40 percent of the total agricultural income per county was from dairying, or where annual county income from dairying equalled or exceeded three-quarters-of-a-million dollars.

In March, 1970, the Agricultural Extension Agent in each selected county conducted interviews with 10 or more randomly selected Grade A dairymen in the county.

Dairymer who were producing 10,400 pounds of milk per year, or more, were classified as high producers, while those producing less than 10,400 pounds of milk per year were classified as low producers. Producers with 59 cows or more were termed large dairymen, while producers with less than 59 cows were classed as small dairymen.

The 21 recommended milk production practices were classified into the following groups of practices: "herd management," "breeding management," "forage feeding," and "concentrate feeding."

Chi square statistical analysis was used to determine the relationship between milk production level and size of herd and of the 21 recommended milk production practices and each of the four groups of practices.

Chi square values that attained the .05 level of probability were accepted as being statistically significant.

Grade A dairy producers' milk production levels were significantly related to 14 of the 21 recommended milk production practices. These 14 practices were: (1) bred the majority of their herd to bulls with a Plus A.I. Proof; (2) provided an adequate amount of stored forage; (3) provided high quality hay and/or silage; (4) fed an all-grain concentrate mixture to the milking herd; (5) fed grain according to production; (6) fed forage based on U. T. recommendations; (7) kept adequate milk production records; (8) maintained adequate herd records; (10) provided sepurate feeding and loafing areas for the milking herd; (11) checked the milking system every six months; (12) prepared each cow properly for milking; (13) obtained the advice of professional diary workers; (14) had at least 75 percent of cows freshen in the fall.

A significantly greater proportion of the producers in the high than in the low milk production group were using each of the 14 recommended milk production practices. Grade A producers' size of herd was significantly related to eight of the recommended milk production practices. These eight practices were: (1) provided an adequate amount of stored forage; (2) provided high quality hay and/or silage; (3) provided an adequate amount of improved pasture; (4) maintained adequate milk production records; (5) maintained adequate herd records; (6) provided separate feeding and loafing areas; (7) checked the milking system every six months; (8) obtained the advice of professional dairy workers.

A significantly greater proportion of the large producers than of the small producers used these eight recommended practices.

A significantly greater proportion of the high producers **than** of of the low producers were using a larger number of "herd management," "breeding management," "forage feeding," and "concentrate feeding" practices.

Size of herd was significantly related to only one group of milk production practices (i.e. "herd management" practices). Producers with large herds tended to use more "herd management" practices than did small producers.

Level of milk production was significantly related to the total number of recommended practices used. Producers with a high level of milk production tended to use more of the 21 practices than did low producers.

Size of herd was not significantly related to the total number of recommended practices used. Large and small dairymen did not differ significantly as to their use of all 21 recommenced practices.

Finally, a significant relationship existed between producers' level of milk production and size of herd. A significantly larger proportion of high producers than low producers had large herds.

A RESEARCH SUMMARY*

I. PURPOSES

The purpose of the study was to determine the relationships between Grade A dairy producers' milk production levels, size of herd and their use of 21 milk production practices recommended by the University of Tennessee. More specifically, objectives of the study were:

- To determine the relationships between Grade A dairy producers' milk production levels and their use of 21 milk production practices recommended by the University of Tennessee.
- 2. To determine the relationships between Grade A dairy producers' herd size and their use of 21 milk production practices recommended by the University of Tennessee.
- 3. To determine the relationships between Grade A dairy producers' milk production levels, herd size and their use of designated Herd Management, Breeding Management, Forage Feeding and Concentrate Feeding practices recommended by the University of Tennessee.

II. METHOD OF INVESTIGATION

Population and Sample

The population consisted of Grade dairymen in 42 Tennessee counties

^{*}Anthony C. Griffin, University of Tennessee, Graduate Student, Agricultural Extension Education Section.

Cecil E. Carter, Jr., Associate Professor, Agricultural Extension Education Section, The University of Tenneseee, Agricultural Extension Service, Knoxville, Tennessee.

Dotson, Robert S., Professor and Head, Agricultural Extension Education Section, The University of Tennessee, Agricultural Extension Service, Knoxville, Tennessee.

which had at least 40 percent of its total agricultural income from dairying and/or counties with an annual income from dairying of at least three-quarters of a million dollars. The "Nth" number technique was used to secure a random sample of at least 10 Grade A producers from each of the 42 Tennessee counties. The sample consisted of 420 Grade A dairymen. Data from 405 of the dairymen were . judged to be accurate and were included in the analyses of the relationships between producers' size of herd and their use of the 21 recommended milk production practices. Information concerning the average pounds of milk produced per cow during 1969 was not available on 14 of the herds, therefore, 391 dairymen were included in the analyses of the relationship between producers' levels of milk production and their use of the 21 recommended milk production practices.

Method of Securing Data

A Grade A Milk Production Practice Checklist, developed by

Specialists at the University of Tennessee, Extension Dairy and Education

Sections, was used to record information concerning milk production

levels, numbers of cows in the dairy herd and use of the 21 recommended

practices. The Agricultural Extension Agent in each of the 42 counties

interviewed the Grade A dairymen in his county and recorded the information on the interview schedule. Interviews were conducted in March

of 1970.

Analysis of Data

The Grade A dairymen were classified into high and low milk production categories. This classification was based upon the average

ERIC Full fext Provided by ERIC

pounds of milk produced in 1969 by the 391 Grade A dairymen. Dairymen who had a herd average above the mean (10,400 pounds of milk was the average for the 391 producers surveyed) pounds of milk were classified as high producers; those with a herd average of 10,400 pounds or less were classified as low producers.

The Grade A dairymen also were classified into large and small producer categories based upon the total number of cows in their herd at the time the interviews were conducted. Producers who had above the mean number of cows (59 cows was the average size of herd for the 405 Grade A dairymen) were classified as small producers.

The 21 recommended milk production practices were classified into the following groups of practices: (1) "Herd Management;" (2) "Breeding Management;" (3) "Forage Feeding," and (4) "Concentrate Feeding." This classification was used only in the analysis included in the final section of the study.

Completed interview schedules were mailed by the County Extension Agents to the Agricultural Extension Education Department. Data were coded and information punched on data cards for analysis by the University of Tennessee Computing Genter.

A Contingency Table Analysis Program (BMDO2S) was used to determine the relationships between milk production level and size of herd and each of the 21 recommended milk production practices. A chi square statistical analysis was used to determine the significance of relationship. Probability levels were read from chi square statistical tables. Chi square values which achieved the .05 level of probability were accepted as statistically significant.

III. REVIEW OF MAJOR FINDINGS

Major findings will be summarized and discussed under four major headings which related to the objectives of the study.

Relationship Between Grade A Dairy Producers' Milk Production Levels and Their Use of 21 Milk Production Practices*

Grade A dairy producers' milk production levels were found to be significantly related (achieved at the .05 level of probability) to 14 of the 21 milk production practices. A high level of milk production was associated with the use of these 14 milk production practices. In other words, a significantly greater proportion of the producers in the high than in the low milk production group were using each of the 14 recommended practices. An average of 18 percent more of the producers in the high milk production group than in the low production group (69 percent of the high and 51 percent of the low) were using each of these 14 recommended practices.

Use of the seven milk production practices which were not significantly related to milk production levels was relatively high for both the high and low production groups of Grade A dairy producers. An average of 77 percent of the producers in the high groups, compared to 76 percent of those in the low milk production group, were using each of the seven other practices.

When Grade A milk producers in the high and the low milk production groups were compared as to their use of all 21 recommended milk production practices, an average of 71 percent of the high milk production group compared to 59 percent of the low group were using each of the 21 recommended practices.

*See Table I in the Appendix.

More specifically, the study showed that a significantly greater proportion of the Grade A dairy producers in the high than the low milk production group: (1) bred the majority of their herd to a bull with a plus A.I. proof (77 vs. 49 percent, respectively); (2) provided an adequate amount of stored forage so that each cow had all the hay and/or silage she could consume every day (92 vs. 73 percents); (3) provided high quality hay and/or silage (83 vs. 63 percents); (4) fed an all-grain concentrate mixture to milking herd (96 vs. 87 percents); (5) fed grain according to production (64 vs. 46 percents); (6) fed forage based on U-T Forage Testing Laboratory recommendations (19 vs. 9 percents); (7) kept adequate milk production records - DHIA, DHIR, OS, or WADAM (48 vs. 14 percents); (8) maintained a 12-14 month calving interval the previous year (94 vs. 85 percents); (9) maintained adequate herd records - heat, health, identification (77 vs. 52 percents); (10) provided separate feeding and loafing areas for milking herd (62 vs. 42 percents); (11) checked the milking system every 6 months to see that it was functioning properly as to pulsation rate and vacuum level (64 vs. 50 percents); (12) prepared each cow properly for milking before the machine was attached (39 vs. 25 percents); (13) obtained the advice of professional dairy workers with regard to herd management (79 vs 62 percents), and (14) bred so that at least 75 percent of cows freshened in the fall (66 vs. 52 percents).

Grade A dairy producers' level of milk production was not significantly related to seven of the 21 milk production practices. Producers with high levels of milk production did not differ from those who had lower herd averages in regard to their use of the following practices:

Relationship Between Grade A Dairy Producers' Size of Herd and Their Use of 2! Milk Production Practices*

Statistical analysis revealed that Grade A dairy producers' size of herd was significantly related to eight of the 21 recommended milk production practices. A significantly larger proportion of the large producers (those with above the mean number of cows-- 59 cows was the mean for all Grade A dairy producers surveyed) than of the small producers used seven of the eight practices. A significantly greater proportion of the small producers than of the large were providing an adequate amount--one to two acres per cow--of improved pasture (66 percent compared to 48 percent respectively). On the average 67 percent of the large producers compared to 56 percent of the small producers were using each of the eight milk production practices which were significantly related to herd size.

*See Appendix, Table II.

More specifically, the study showed that a significantly greater proportion of the large than of the small producers: (1) provided an adequate amount of stored forage so that each cow had all the hay and/or silage that she could consume every day (90 vs. 77 percents, respectively); (2) provided high quality hay and/or silage (82 vs. 66 percents); (3) kept adequate milk production records last year (43 vs. 24 percents); (4) maintained adequate herd records - heat, health, identification (72 vs. 60 percents); (5) provided separate feeding and loafing areas for the herd (66 vs. 43 percents); (6) checked their milking system every six months to see that it was functioning properly as to pulsating rate and vacuum level (65 vs. 51 percents), and (7) obtained the advice of professional dairy workers with regard to management of the herd (70 vs. 64 percents).

Concerning 13 of the milk production practices which were not significantly related it was found that an average of 69 percent of the larger producers compared to 67 percent of the smaller producers were using each of the 13 practices. On eight of these 13 practices a greater proportion (i.e. not significant at the .05 level of probability) of the large than the small producers were using the recommended practices. Conversely, on the remaining five of the 13 practices an equal or greater percent of the small than of the large producers (not significant at the .05 level of probability) were using the recommended practices.

More specifically concerning the milk production practices which failed to achieve the .05 level of probability, the eight practices which were used by a greater proportion of the large than of the small producers

were as follows: (1) bred a majority of the herd to a bull with A.I. proof (68 vs. 60 percents, respectively); (2) bred heifers to freshen at 24 - 27 months of age (85 vs. 79 percents); (3) allowed a period of at least 60 days following calving for each cow prior to breeding (95 vs. 93 percents); (4) provided an adequate amount of summer pasture (44 vs. 39 percents); (5) fed an all-grain concentrate mixture to milking herd (94 vs. 90 percents); (6) fed grain according to production (56 vs. 54 percents); (7) fed forage based on U. T. recommendations last year (18 vs. 12 percents), and (8) provided an average dry period of 60 days per cow (89 vs. 87 percents).

The five milk production practices which were used by an equal or a larger proportion of the small producers (not significant at the .05 level of probability) were as follows: '(1) maintained a 12-14 month calving interval (90 vs. 88 percents, respectively); (2) raised at least 75 percent of herd replacements (81 /3. 81 percents); (3) prepared each cow properly for milking before the machine was attached (33 vs. 31 percents); (4) systematically used a recommended method of fly control around barns, loafing and milking areas (91 vs. 87 percents), and (5) at least 75 percent of cows freshened in the fall last year (61 vs. 58 percents).

Relationships Between Grade A Dairy Producers' Milk Production

Levels and Their Use of Groups of Practices Concerning "Herd

Management," "Breeding Management," "Forage Feeding" and

"Concentrate Feeding" Practices.*

The 21 recommended milk production practices were grouped into *See data in Tables III, IV, V and VI. four categories (i.e. "herd management," "breeding management," "forage feeding" and "concentrate feeding" practices) in order to determine whether producers in the high and low level of milk production groups, differed as to their use of specific kinds of milk production practices. This analysis revealed that a significantly larger proportion of the producers in the high milk production category, than those in the low milk production category, were using a larger number of the "herd management," "breeding management," "forage feeding," and "concentrate feeding" practices.

Relationships Between Grade A Dairy Producers Size of Herd and

Their Use of Groups of Practices Concerning "Herd Management,"

"Breeding Management," "Forage Feeding" and "Concentrate Feeding"

Practices*

The 21 recommended milk production practices also were grouped into four categories in order to determine whether producers with large and with small herd sizes differed in their use of specific kinds of milk production practices. Size of herd was significantly related only to one group of milk production practices (i.e. herd management practices). Producers with large dairy herds used more of the herd management practices than did the small producers. Although not significant at the .05 level of probability there was a tendency also for the large producers to use more of the "breeding management," "forage feeding" and "concentrate feeding" practices.

When all 21 practices were analyzed as to their use by producers with high levels of milk production, it was found that production level *See data in Tables VII, VIII, IX and X.

was significantly related to the total number of recommended milk production practices used. Producers with high production levels tended to use more of the 21 practices than did those with low production levels.

Comparison of the large and the small producers as to their use of the total for all 21 of the recommended practices showed that they did not differ significantly (i.e. at the .05 level of probability).

Finally, analysis of the data indicated that a significant relationship existed between producers' levels of production and their size of herd. A significantly larger proportion of the high producers (50 percent) than of the low producers (28 percent) had large herds. Conversely, the low producers tended to have smaller dairy herds.

Name	Address
Coun t	y Date Tenure Status No
To tal	number of cows in herd Number registered Number Grade
Herd	average Lbs. milk Lbs. fat
	RECOMMENDED PRACTICE YES NO
1.	Was the majority of your herd bred to a bull with a plus A.I. (artificial insemination) proof last year (i.e., his artificially sired daughters' production exceeded that of their herdmates?)
2.	Were heifers bred to freshen at 24-27 months of age?
3.	Was a period of at least 60 days following calves allowed each cow prior to breeding?
4.	Was an adequate amount of stored forage provided so that each cow had all the hay and/or silage that she could consume every day.
5.	Was high quality hay and/or silage (alfalfa-bud to 1/10 bloom stage; grasses and small grainsin the boot to early bloom stage; corn for silagein the dent stage) provided last year?
6.	Was an adequate amount (1 to 2 acres per cow) of improved pasture (e.g., Ladino and orchard grass) provided last year?
7.	Was an adequate amount of summer pasture (1/4 to 1/2 acre per cow) provided?
8.	Was an all-grain concentrate mixture (i.e., one not containing ground hay, etc.) fed to your milking herd?
9.	Was grain fed according to production with special attention to assure that high producers got enough grain (i.e., 1 to 3 or 1 to 4)?

	RECOMMENDED PRACTICE	YES	NO _
10	Was forage fed last year based on U.T. Forage Testing Laboratory recommendations?		
11.	Were adequate milk production records kept last year (DHIA, DHIR, OS, or WADAM)?		
12.			·
13.	Was a 12-14 month calving interval maintained last year?		
14.	Did you raise at least 75% of herd replacements?		
15.			····
16.	Were separate feeding and loafing areas provided for milking herd?		
17.	Was the milking system checked every 6 months to see that it was functioning properly as to pulsation rate and vacuum level?		
18.	Was each cow prepared properly for milking (including the use of a strip cup or its equivalent, on each quarter) before the machine was attached?		
19.	Was a recommended method of fly control systematically used around barns, loafing and milking areas?		<u> </u>
20.	Was the advice of professional dairy workers obtained with regard to management of your herd?		
21.	Did at least 75% of your cows freshen in the fall last year?
